MCP pilot: decision summary

Summary

We propose a time-boxed pilot of Model Context Protocol (MCP) servers to let internal AI assistants reach approved tools and data through one standard interface, replacing one-off integrations. The pilot tests whether this reduces integration effort without weakening access controls.

Scope

Six-week pilot, read-mostly access, limited to three use cases and a small group of volunteer users. Production write access and customer-facing deployment are out of scope.

Pilot use cases

Use case	Description	Owner
Engineering issue triage	Assistant reads error and ticket data to draft triage notes	[Owner TBC]
Document search	Assistant searches approved shared drives for answers	[Owner TBC]
Calendar and scheduling	Assistant proposes meeting times from calendars	[Owner TBC]

Risks

Data exposure: servers may surface more data than intended; mitigate with least-privilege scopes. **Untrusted content:** tool outputs can carry prompt injection; keep write actions behind human approval. **Operational load:** each server needs an owner and monitoring.

Decision needed

Approve or decline the six-week pilot as scoped, and confirm a named owner for each use case above.
